

Title is WIP. I think it should make it clear that it's an idle game. Ideally it should draw attention to the difficulty slider by playing on the word "normal".

In the perfect word it would be a slogan that suggest virtue signaling, i.e. "save the planet and keep your comfort", but also subtly imply "you need to overthrow the norm"

Other ideas:

Save your life/sinking ship

Centrist/moderate/capitalist/status quo simulator

broken/rigged/fixed/impossible mode/game/system

Reform/patch up/bandaids on an open wound (lifeboats??)

Normal Idle

A game about the violence of inaction

CREDITS

Choose difficulty

EASIER TIMES

NORMAL

The default option
(recommended setting)

NEW NORMAL

POST NEW NORMAL

IMPOSSIBLE

Extreme challenge with more options for people who are ready to tackle an impossible fight

Indicative narrative blurb to hint at the path to victory. Needs to be carefully wordsmithed. Possibility to force the player to play NORMAL one time before allowing change by greying out options.

"Reforms" that the player can chose. They each cost "human points" and increase "human point income".

Each option unlocks further options like a tech tree in civilization, so that the player has stuff to explore and try out.

I'm thinking of getting option ideas from global warming research like drawdown.org. I know it's not the be-all-end-all of anti-capitalism but I think it's a pretty solid start and easy to convert into objective scores. We may want a disclaimer about that in the credits xD

Main game loop (~5 min)

Option 1 -1RP, +1RP/s

Option 2 -3RP, +5RP/s

Option 3 -10RP, +20RP/s

Reform Points:

10

+1RP/s

Names
TBC

Crisis Points:

11

Exponential-like growth, always above human point in base game

MATH

Reform - Crisis:

-1 (human/s)

Always in red

Population:

7 000 000 000

LOSE
When
pop = 0

Year 2031

Illustration?
(planet,
ect)

Special set of stronger options

WIN when Reform > Crisis

Do you want to dismantle existing institutions? It will cause extra difficulty.

NO / YES

With this, the game starts with a pretty bad malus initially, but it also unlocks the possibility to do much stronger reforms and ultimately win if you survive the initial chaos.

This also needs to be written pretty carefully. We can have a few more questions/options but it needs to remain vague because I don't have the perfect recipe for success and we don't want to be too prescriptive.

"Expert" onboarding

Tech tree

	# licent	time	cash on hand	pps	->	income
T1	1	10	10	10		90
T2	10	50	15			300
T3	30	200	25			750
T4	60	500	40			1.2K
	90	750	50			1.5K
T5	120	1.0K	500			15.0K
	150	10.0K	2.5K			75.0K

Data model

Math/balance

```

Pop de depart: 7b in 2013, 8b 2024
rate = 1000000000/((new Date("2024/01/01")).getTime() - (new Date("2013/01/01")).getTime())
pop = 8106672020 + ((new Date()).getTime() - (new Date("2024/05/02")).getTime()) * rate
    
```

Crisis point = seconds ^ 4
 8 billions at 5min

 Reform points = seconds ^ 3 max, only 27m at 5min.
 Derivative is squared

 Expected reform point / sec = 2.5 * seconds ^ 2

 Average price of a single RPs : 0.01 RP (10RP buys you 1kRPs on average, mb at max)
 From exponential modeling, 1RPs = 0.07 RP

 RPs = 2 * POW(RP, 0.6)

 Expect a purchase e

notes

Mb effect of the difference between the scores affects the population more rarely like every 10 secs . Instead of differential being subbed from pop, have it be added to "counter before next death", that will make bundling easy

C'est la même chose avec un multiplicateur caché je crois je devrais pas avoir besoin de deux système de timer c'est juste les décimales de la population

Temps de remboursement = prix / vitesse

Accélération max = vitesse / temps remboursement = $v/(p/v) = v^2/P$

Acceleration quadratique en v

Si prix proportionnel à vitesse par facteur alpha $P = \alpha v$, $\text{Acc} = v/\alpha = \text{dérivée de } v \text{ donc en intégrant } v = \text{const} * t^2$

$V(t) = \text{sum}(\text{all } v\text{'s})$

Expected money is $t^3 Rly$

$V=t^2$, $c=t^3$ $V^3=c^2$ Cost = grain to the power $3/2$

(diff time to pay up) = durée du jeu

Diff time to pay up = $(c_2-c_1)/(v_2-v_1)$

Durée de rentabilité should be around 20/30 sec so $20 v = \text{cost}$

5min

$V=c/t$

Cost = 5 v

$T_0 = c_0/v_0$

$C_2/v_1 + (c_1)/(v_1+v_2)$

That's the equilibrium between choice 0 and choice 1+2

Tout keep homologué à $c_0 = v_0 * 30s$ Si $C_0 = 10 v_0 = . 3pps$

Après un choix entre 0 et 1+2 le cash à l'instant t est $\text{Cash} = v_0 * t = v_1 * t + v_2 * (t - c_2/v_1)$

$30v_0 = 30v_1 + 30v_2 - v_2 c_2/v_1$ $V_2 c_2 / v_1$ est un cout

$\text{Cash} = v_0 * t = v_1 * t + v_2 * (t - c_2/v_1) = v_1 * t + v_2 * t - v_2 * c_2 / v_1$

Pour être équivalent à +1pps pour 30 (option 1) l'option 2 à +. 5ppa devra coûter c_2 where Avec v_0 1pps

$30s = c_1/v_0 + c_2/(v_0+v_1)$

$= c_1 + c_2/1.5$

Si c_1 est 20 c_2 est 15 pour $v_2 = . 5ppa$

Semblerait que le decay soit en 3/4 entre deux purchase du même v

60 choix donne en moyenne 5s entre chaque choix

1 nouvelle option tous les 5 secondes quoi

$V(t) = . 1 t^2$

Pick your centrisme level low lvl hides death high level hides negative numbers

And survivor bias mode that hides all negative values?

Add a centrist mode that hides death notification for sure
